WESTERN SPRUCE BUDWORM IMPACT EVALUATION PAYETTE AND BOISE NATIONAL FORESTS AND IDAHO DEPARTMENT OF LANDS

Ъy

Max M. Ollieu¹, Ladd Livingston², and Wayne E. Bousfield³

INTRODUCTION

The present outbreak of western spruce budworm, Choristoneura occidentalis, Freeman, on the Payette National Forest began in 1968 near Brundage Mountain. The infestation, which now occurs over approximately 900,000 acres of mixed conifer type, also includes portions of Boise National Forest, state, private and other federal lands. Knopf (1977) reported on the status of western spruce budworm in these areas.

Assistance was requested and received from Forest Insect and Disease Management (FIDM), R-1, Missoula, to help conduct an impact survey of affected forest stands similar to that completed by Bousfield (1975). The authors conducted the field portion of the survey in September 1976 and the data management portion was completed by FIDM, Missoula, in October 1976. Analysis of those results are reported in this evaluation.

METHODS

Three general sites were chosen for the impact study which had all experienced heavy defoliation in 1976. The first was on Brundage Mountain north of McCall which for the most part fell within the McCall Ranger District, Payette National Forest. This area had the oldest recorded infestation; approximately eight years. The second site was on State lands approximately five miles southeast of McCall. The outbreak had persisted in this area approximately six years. The third site was chosen on the Cascade Ranger District, Boise National Forest. This area has had four years of defoliation.

Using aerial resource photography, five stands from within the commercial forest component of each of the three sites were selected for sampling. They were chosen to represent as wide a range of species composition, age class and spacing as possible.

Two-man crews were employed to collect data from each stand. A compass and tape were used to establish plot centers every five chains with ten chains between cruise strips. Plot centers were common to two types of plots:

Entomologist, Insect & Disease Control, Forest Service, Boise, Idaho.

²Forest Entomologist, Department of Lands, State of Idaho, Coeur d'Alene, Idaho.

³Entomologist, Forest Insect & Disease Management, Forest Service, Missoula, Montana.

(1) a variable plot which considered all trees 5 inches dbh and over and (2) a fixed plot which accounted for all trees under 5 inches dbh.

Each variable plot represented 5 acres of the stand. A relaskop was used to select plot trees and measure their heights. A BAF of 40 was used for all stands. In addition to height, data on tree species, dbh and damage class ratings were also recorded. Damage class ratings were assigned a value from 0-6:

0 = no defoliation

1 = current year defoliation

2 = current plus older defoliation

3 = 10% or less top kill

4 = 11 to 33% top kill

5 = more than 33% top kill.

6 = tree mortality by budworm

Fixed plots were used to survey numbers, species and damage class ratings of all trees under 5 inches dbh. Plots were circular and 1/300 acre in size: 6.8 feet radius.

Radial growth data were collected from two stands. Increment cores were taken from three trees nearest each plot center 5 inches dbh or larger until approximately 20 trees of three different species had been sampled. Radial growth measurements were recorded for the period of most recent defoliation and a corresponding measurement for previous years of normal growth. A binocular scope was used to measure each core. Covariance analysis was used to adjust radial growth means and enable comparisons of the three tree species.

RESULTS

Data from the impact evaluation are presented in tables 1-8. Variable plot data are contained in tables 1-4, which display volume and trees per acre 5 inches dbh and greater by species and damage class. Fixed plot data are presented in tables 5-8, which display trees per acre less than 5 inches dbh by species and damage class.

Variable plots

Data from the 14 stands show average volume to be 23,741 bd. ft. and 207 trees per acre (Table 1). Top kill occurred in 34 percent of the 5 inch dbh and greater trees. Mortality attributed to defoliation by budworm was recorded in only .07 percent of the trees.

Grand fir constituted over half of the volume and number of trees in the stands. Grand fir also displayed the most injury with 53 percent top kill in the 5 inch dbh and greater category and 1.1 percent dead (Figure 1). No mortality attributed to defoliation by budworm occurred in any other trees species. Subalpine fir also showed top killing but this species was only a minor component of the stands sampled. A minor amount of top kill was also recorded for Douglas-fir and Engelmann spruce. Western larch, lodge-pole and ponderosa pine showed no defoliation, top killing or mortality from western spruce budworm.

The five stands sampled on the McCall Ranger District, Payette National Forest were in the area where defoliation commenced eight years prior. Strangely, those stands had the least percent of top killed trees: 27 percent in the 5 inches and greater category (Table 2). The State of Idaho lands with trees defoliated 6 years had 30 percent top kill (Table 3). The stands on the Cascade Ranger District, Boise National Forest, with only 4 years defoliation were 50 percent top killed (Table 4).

Stands sampled on the Cascade Ranger District contained the highest average volume, 31,685 bd. ft. per acre and lowest number of trees 5 inches dbh and greater: 152. Grand fir 5 inches dbh and greater comprised a larger component of the stand (69% volume, 74% trees) on the Cascade Ranger District than Payette National Forest or State of Idaho stands sampled.

Fixed plots

Data from the 14 stands for trees less than 5 inches dbh show an average of 791 trees per acre with 8 percent top kill (Table 5). Grand fir composed 69 percent of the trees and also suffered the most top kill. However, Douglas-fir and spruce which made up 13 and 12 percent of the stems respectively suffered top kill proportionately as high as grand fir.

Five stands sampled on the McCall Ranger District for trees under 5 inches dbh contained 660 stems per acre with 7 percent top kill (Table 6). Grand fir, Engelmann spruce and Douglas-fir all displayed top kill. State lands contained 620 stems per acre less than 5 inches with 6 percent top killed (Table 7). Grand fir and Engelmann spruce were also top killed. The Cascade Ranger District had 1091 trees per acre less than 5 inches and 9 percent top killed (Table 8). The Cascade Ranger District stands had the highest amount of grand fir regeneration, 80 percent. Both grand fir and Douglas-fir showed top killing.

Radial Growth Measurements

Increment core extractions to measure radial growth at one stand on the McCall Ranger District showed grand fir to be growing 94 percent of normal for the last five years. The area has been defoliated for eight years. Core extractions from another stand on State of Idaho lands showed

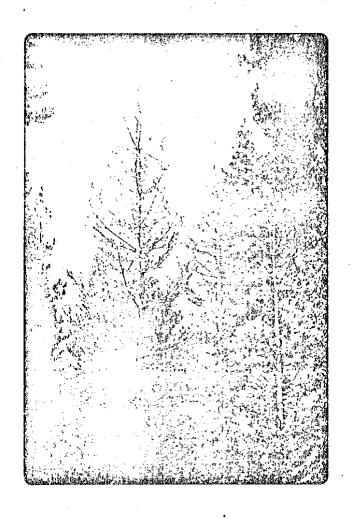

Figure 1. Grand fir top killed from defoliation by western spruce budworm, McCall R.D., Payette NF, 1976.

grand fir to be growing 74 percent of normal for the last three years. This area has been defoliated for six years. Ponderosa pine and Douglas-fir showed no radial growth reduction in either stand. Core measurements indicate growth reduction begins 2-3 years after initial defoliation.

Timber survey data from plots in the McCall area show grand fir stands produce 263 Bd.Ft./A/Yr. With average growth reduction of 16 percent in defoliated stands of grand fir then radial growth loss would equal 42 Bd.Ft./A/Yr. in the McCall area.

DISCUSSION

Stocking of conifers in the 14 stands sampled averaged 998 stems per acre with 207 trees 5 inches dbh and greater, and 791 under 5 inches dbh. These data indicate that stands are adequately stocked to overstocked. Top killing has occurred in 34 percent of trees 5 inches dbh and greater: 29 percent grand fir, 2 percent Engelmann spruce, 2 percent subalpine fir and 1 percent Douglas-fir. Top killing of trees under 5 inches dbh has occurred in 8 percent of the trees: 6 percent grand fir, 1 percent Douglas-fir and 1 percent Engelmann spruce. Mortality has been insignificant with less than 0.1 percent of trees 5 inches dbh and above killed by budworm feeding. Radial growth loss has only been recorded in grand fir with an average 16 percent slowdown in growth or 42 Bd.Ft./A/Yr. radial growth loss.

Top killing was severe in grand fir sapling and pole-sized trees particularly where a grand fir overstory was present. Deformation, multi-tops, and infection by decay fungi in this top killed grand fir regeneration will continue to impact commercial volume produced over the rotation of the stand. Removal of overstory, particularly grand fir, and thinning of top killed trees will help keep growth loss from budworm feeding to as low a level as possible.

Cascade Ranger District stands displayed the most damage from budworm feeding. They contain the highest percentage of grand fir trees, 79, the most stems per acre, 1,243, highest volume, 31,685 Bd.Ft./A, and have been defoliated the least number of years, four, when compared to the other two areas sampled. These figures apparently would also support decisions to reduce grand fir overstory and percent of the species in the stand.

Knopf (1977) predicted defoliation by western spruce budworm to continue in 1977 similar to that experienced in 1976. If that prediction holds true, the infestation area will probably expand and damage intensify. Top killing will increase, radial growth in grand fir will slow somewhat more and tree mortality will become more apparent. Additional grand fir will become unsuitable as future crop trees and cone crops of susceptible species will be poor or nonexistent.

RECOMMENDATIONS

- 1. Land managers with stands defoliated by western spruce budworm should examine resource values involved and determine if changes in management may be necessary.
- 2. Silvicultural techniques which can reduce damage by budworm include: (1) removal of grand fir overstory, (2) shortening rotation, (3) diversifying composition to favor non-host species and (4) removal of top killed regeneration.
- 3. Payette and Boise Forest personnel should complete section III of the Environmental Impact Statement as outlined in the Regional Forester's letter of October 22, 1976.
- 4. Land managers should cooperate with personnel from Insect and Disease Control and Forest Insect Research on pilot projects and field experiments of promising insecticides.
- 5. Insect and Disease Control personnel should conduct an aerial detection survey, parasite survey, egg mass survey and expanded stand impact survey in 1977 to provide land managers with pertinent information on budworm activity.
